

# What To Look For to See If Your Child Has GDD?

Skills development in children should begin at a certain age. For example, a newborn can start rolling over and performing similar motions about four or five months, possibly earlier or later.

However, if a baby is unable to move much after completing the stated milestone, is unable to hold up their head, or is still not "babbling," these may be the first indicators of a general developmental delay.

To compare your child's progress to average developmental milestones, complete the checklist below:

- By three to four months old, the newborn should be able to respond to loud stimuli. The child should be able to murmur and imitate sounds.
- Around seven months of age, the baby should begin to respond to sounds.
- At the age of one, the infant should begin uttering simple words like "mama".

- At age two, the infant should be able to say at least 15 words. It should be able to communicate in brief, usually two-word sentences without mimicking or repeating others. Instead of acting out their requests, the youngster should usually speak to convey them.

If your kid does not display these typical developmental changes, it is likely that he or she has a global developmental delay.
